
Some Examples of the PKCS Standards

An RSA Laboratories Technical Note

Burton S. Kaliski Jr.

Revised November 1, 1993*

Abstract. This document gives some examples of PKCS. The reader is assumed to be familiar with the members of the PKCS family, or at least to have read the PKCS overview.

1. Introduction

This document illustrates some of the PKCS standards with the following sequence of examples:

1. An example user, called "Test User 1," generates an RSA key pair according to PKCS #1 and protects the private key with a password according to PKCS #5 and #8.
2. The user prepares a PKCS #10 certification request and obtains a certificate.
3. The user prepares a digitally signed message according to PKCS #7.

In the examples, long integers are written in hexadecimal, most significant octet first. As usual, BER encodings are displayed as hexadecimal octet strings. All BER encodings in this document are also DER encodings.

2. Generating a key pair and protecting the private key

The process of generating a key pair and protecting the private key breaks down into five steps:

1. Generating an RSA key pair according to PKCS #1.
-

*Supersedes June 3, 1991 version, which was also published as NIST/OSI Implementors' Workshop document SEC-SIG-91-25. PKCS documents are available by electronic mail to <pkcs@rsa.com>.

2. Encoding values of type `RSAPublicKey` and `RSAPrivateKey` according to PKCS #1 to represent the key pair in an algorithm-specific way.
3. Encoding values of type `PrivateKeyInfo` according to PKCS #8 to represent the private key in an algorithm-independent way.
4. Encrypting the `PrivateKeyInfo` encoding with a password according to PKCS #5.
5. Encoding a value of type `EncryptedPrivateKeyInfo` according to PKCS #8 to represent the encrypted `PrivateKeyInfo` value in an algorithm-independent way.

2.1 Generating an RSA key pair

Test User 1 generates an RSA key pair according to PKCS #1.

In the example, the modulus n is the following 508-bit integer:

```
n = 0a 66 79 1d c6 98 81 68 de 7a b7 74 19 bb 7f b0 c0 01 c6 27 10 27 00
75 14 29 42 e1 9a 8d 8c 51 d0 53 b3 e3 78 2a 1d e5 dc 5a f4 eb e9 94 68
17 01 14 a1 df e6 7c dc 9a 9a f5 5d 65 56 20 bb ab
```

The prime factors p and q of the modulus are:

```
p = 33 d4 84 45 c8 59 e5 23 40 de 70 4b cd da 06 5f bb 40 58 d7 40 bd 1d
67 d2 9e 9c 14 6c 11 cf 61
```

```
q = 33 5e 84 08 86 6b 0f d3 8d c7 00 2d 3f 97 2c 67 38 9a 65 d5 d8 30 65
66 d5 c4 f2 a5 aa 52 62 8b
```

The public exponent e is F_4 (65537):

```
e = 01 00 01
```

The private exponent d and other private-key parameters are as follows:

```
d = 01 23 c5 b6 1b a3 6e db 1d 36 79 90 41 99 a8 9e a8 0c 09 b9 12 2e 14
00 c0 9a dc f7 78 46 76 d0 1d 23 35 6a 7d 44 d6 bd 8b d5 0e 94 bf c7 23
fa 87 d8 86 2b 75 17 76 91 c1 1d 75 76 92 df 88 81
```

```
d mod p-1 = 04 5e c9 00 71 52 53 25 d3 d4 6d b7 96 95 e9 af ac c4 52 39
64 36 0e 02 b1 19 ba a3 66 31 62 41
```

```
d mod q-1 = 15 eb 32 73 60 c7 b6 0d 12 e5 e2 d1 6b dc d9 79 81 d1 7f ba
6b 70 db 13 b2 0b 43 6e 24 ea da 59
```

```
q1 mod p = 2c a6 36 6d 72 78 1d fa 24 d3 4a 9a 24 cb c2 ae 92 7a 99 58
af 42 65 63 ff 63 fb 11 65 8a 46 1d
```

2.2 Encoding RSAPublicKey and RSAPrivateKey values

Test User 1 encodes values of type RSAPublicKey and RSAPrivateKey according to PKCS #1 to represent the key pair in an algorithm-specific way.

The BER-encoded RSAPublicKey value is:

```

30 47
 02 40                               modulus = n
    0a 66 79 1d c6 98 81 68 de 7a b7 74 19 bb 7f b0
    c0 01 c6 27 10 27 00 75 14 29 42 e1 9a 8d 8c 51
    d0 53 b3 e3 78 2a 1d e5 dc 5a f4 eb e9 94 68 17
    01 14 a1 df e6 7c dc 9a 9a f5 5d 65 56 20 bb ab
 02 03 01 00 01                      publicExponent = e

```

The RSAPublicKey value is later used in a certificate.

The BER-encoded RSAPrivateKey value is:

```

30 82 01 36
 02 01 00                               version = 0
 02 40                               modulus = n
    0a 66 79 1d c6 98 81 68 de 7a b7 74 19 bb 7f b0
    c0 01 c6 27 10 27 00 75 14 29 42 e1 9a 8d 8c 51
    d0 53 b3 e3 78 2a 1d e5 dc 5a f4 eb e9 94 68 17
    01 14 a1 df e6 7c dc 9a 9a f5 5d 65 56 20 bb ab
 02 03 01 00 01                      publicExponent = e
 02 40                               privateExponent = d
    01 23 c5 b6 1b a3 6e db 1d 36 79 90 41 99 a8 9e
    a8 0c 09 b9 12 2e 14 00 c0 9a dc f7 78 46 76 d0

    92 7a 99 58 af 42 65 63 ff 63 fb 11 65 8a 46 1d

```

2.3 Encoding a PrivateKeyInfo value

Test User 1 encodes a value of type PrivateKeyInfo according to PKCS #8 to represent the private key in an algorithm-independent way.

In this example, the private key is identified by PKCS #1's `rsaEncryption`, which has the object identifier value `{ 1 2 840 113549 1 1 1 }`. There are no attributes in the private-key information.

The BER-encoded `PrivateKeyInfo` value is the following 340-octet string:

```

30 82 01 50
 02 01 00           version = 0
 30 0d
  06 09
    2a 86 48 86 f7 0d 01 01 01
  05 00           parameters = NULL
 04 82 01 3a
 30 82 01 36 ... 65 8a 46 1d      privateKey = RSAPrivateKey encoding

```

2.4 Encrypting the PrivateKeyInfo encoding

Test User 1 encrypts the `PrivateKeyInfo` encoding with a password according to PKCS #5.

In this example, the selected password-based encryption algorithm is "MD2 with DES-CBC." There are three steps to this algorithm: a DES key and initializing vector are derived from the password with MD2, given a salt value and an iteration count; the `PrivateKeyInfo` encoding is padded to a multiple of eight bytes; and the padded `PrivateKeyInfo` encoding is encrypted under DES.

The message M is the `PrivateKeyInfo` encoding.

The password P is the ASCII string "password":

$P = 70\ 61\ 73\ 73\ 77\ 6f\ 72\ 64$

The salt value S (which happens to be derived deterministically from the MD2 message digest of the octet string $P \parallel M$) is:

$S = 53\ 7c\ 94\ 2e\ 8a\ 96\ 04\ 4b$

The iteration count c is 1.

The result of one iteration of MD2 on the octet string $P \parallel S$ is the following 16-octet string:

$13\ 1a\ 55\ 51\ fe\ 1f\ d2\ a4\ 3a\ d9\ 95\ 74\ 66\ 6b\ 67\ ce$

The DES key K (with odd parity) and the initializing vector IV derived from the message digest are:

$K = 13\ 1a\ 54\ 51\ fe\ 1f\ d3\ a4$

IV = 3a d9 95 74 66 6b 67 ce

The padding string *PS* for the message *M* is

PS = 04 04 04 04

since the length of the message *M* is 340 octets, which is four less than a multiple of eight.

The ciphertext *C* resulting from encrypting the octet string *M* || *PS* under DES with key *K* and initializing vector *IV* is the following 344-octet string:

```
20 d4 dd 6a 50 5f 0d ea e3 da a6 98 22 a0 10 0e 70 ef e2 8f 4b 07 ff ee

fe 71 b6 b3 7e 71 c8 cf
```

2.5 Encoding the EncryptedPrivateKeyInfo value

Test User 1 encodes a value of type `EncryptedPrivateKeyInfo` according to PKCS #8 to represent the encrypted `PrivateKeyInfo` value in an algorithm-independent way.

In this example, the encryption algorithm is identified by PKCS #5's `md2WithDES-CBC`, which has the object identifier value {1 2 840 113549 1 5 1}.

The BER-encoded `EncryptedPrivateKeyInfo` value is:

```
30 82 01 78
 30 1a
    06 09
      2a 86 48 86 f7 0d 01 05 01
    30 0d
      04 08 53 7c 94 2e 8a 96 04 4b
      02 01 01
    04 82 01 58
      20 d4 dd 6a ... 7e 71 c8 cf
```

encryptionAlgorithm	
algorithm =	pbeWithMD2AndDES-CBC
parameter	
salt value	
iteration count = 1	
encryptedData	

Test User 1 can now store this encoding and transfer it from one computer system to another. The private key is obtained by reversing steps 3, 4 and 5.

3. Obtaining a certificate

The process of obtaining a certificate breaks down into three steps:

1. Encoding a value of type CertificationRequestInfo according to PKCS #10 from Test User 1's name and public key.
 2. Signing the CertificationRequestInfo encoding.
 3. Encoding a value of type CertificationRequest according to PKCS #10 from the CertificationRequestInfo value and the signature.

The certification authority's steps are not considered, although the resulting certificate is described.

3.1 Encoding a CertificationRequestInfo value

Test User 1 encodes a value of type `CertificationRequestInfo` according to PKCS #10 from its name and public key. In this example, the name is the common name "Test User 1" within the organization "Example Organization" within the country "US." The public key is identified by PKCS #1's `rsaEncryption`. There are no attributes in the certification request information.

The BER-encoded CertificationRequestInfo value is:

```
30 81 a4
02 01 00
30 42
31 0b
30 09
06 03 55 04 06

attributeType = commonName
attributeValue = "Test User 1"

30 5b
30 0d
06 09
2a 86 48 86 f7 0d 01 01 01
05 00
subjectPublicKeyInfo
algorithm
algorithm = rsaEncryption
parameters = NULL
```

```

03 4a                      subjectPublicKey = RSApublicKey encoding
 00 30 47 02 40 ... 03 01 00 01

```

3.2 Signing the CertificationRequestInfo encoding

Test User 1 signs the CertificationRequestInfo encoding with its private key.

In this example, the selected signature algorithm is PKCS #1's md2WithRSAEncryption. There are three steps to this algorithm: An MD2 message digest is computed on the CertificateInfo encoding, then the message digest is encoded as a DigestInfo value, then the DigestInfo encoding is encrypted under RSA with Test User 1's private key. (Section 4.4 gives a more detailed example of RSA private-key encryption.)

The message digest is:

```
dc a9 ec f1 c1 5c 1b d2 66 af f9 c8 79 93 65 cd
```

In this example, the message-digest algorithm in the DigestInfo value is identified by RFC 1321's md2, which has the object identifier value {1 2 840 113549 2 2}.

The BER-encoded DigestInfo value is:

```

30 20
  30 0c                               digestAlgorithm
    06 08 2a 86 48 86 f7 0d 02 02   algorithm = md2
    05 00                               parameters = NULL
  04 10                               digest
    dc a9 ec f1 ... 79 93 65 cd

```

RSA encryption according to PKCS #1 has two general steps: An encryption block is constructed from a block type, a padding string, and the prefixed message digest; then the encryption block is exponentiated with Test User 1's private exponent.

The encryption block *EB* is the following 64-octet string:

00		block type
01		padding string
ff		
ff		
00		00 separator
30 20 30 0c ... 79 93 65 cd		data D

The resulting encrypted message digest (the signature) is the following 64-octet string:

```

06 db 36 cb 18 d3 47 5b 9c 01 db 3c 78 95 28 08
02 79 bb ae ff 2b 7d 55 8e d6 61 59 87 c8 51 86
3f 8a 6c 2c ff bc 89 c3 f7 5a 18 d9 6b 12 7c 71
7d 54 d0 d8 04 8d a8 a0 54 46 26 d1 7a 2a 8f be

```

3.3 Encoding a CertificationRequest value

Test User 1 encodes a value of type CertificationRequest according to PKCS #10 from the CertificationRequestInfo value and its signature.

The BER-encoded CertificationRequest value is:

```

30 81 f9
  30 81 a4 02 ... 03 01 00 01           certificationRequestInfo
  30 0d                                     signatureAlgorithm
    06 09                                     algorithm = md2WithRSAEncryption
      2a 86 48 86 f7 0d 01 01 02
    05 00                                     parameters = NULL
  03 41                                     signature
    00 06 db 36 cb ... 7a 2a 8f be

```

Test User 1 can now send the encoding to a certification authority to obtain a certificate.

3.4 The certificate

In this example, the certificate is as follows:

- The version is 0. (Since this is the default, the field is not included in the encoding.)
- The serial number is 14000029 (hexadecimal).
- The signature algorithm is PKCS #1's md5WithRSAEncryption, which has the object identifier value {1 2 840 113549 1 1 5}.
- The issuer's distinguished name is the organization "Example Organization" within the country "US."
- The name is Test User 1's name from the certification request.
- The validity period is from 10:18:06pm GMT, September 9, 1992 to 10:18:05pm GMT, September 9, 1994.
- The public key is Test User 1's public key from the certification request.

The BER-encoded Certificate value is:

```

30 82 01 5a
30 82 01 04                               certificateInfo
02 04 14 00 00 29                         serialNumber = 14000029
30 0d                                     signature
06 09                                     algorithm = md2WithRSAEncryption
2a 86 48 86 f7 0d 01 01 02
05 00                                     parameters = NULL

```

The BER-encoded RSAPublicKey value for Example Organization's key is:

```

30 48
02 41                                     modulus
00 c5 59 65 91 f6 70 ac 38 7f ba bf f6 c0 d0 83
e5 93 22 0e 0b c3 a0 0f 97 5b 9e b7 ad 51 4c 77
7b ae 14 25 2d f8 30 58 74 7f 17 7e ac 9c 1d a5
39 4d 33 eb d8 de 92 16 a4 1c 69 d2 d4 83 8f a4
51
02 03 01 00 01                           publicExponent

```

The certificate signature can be verified with Example Organization's public key. Example Organization's private key is stored in secure hardware at RSA Data Security.

4. Preparing a digitally signed message

The process of preparing a digitally signed message breaks down into six steps:

1. Encoding a value of type ContentInfo according to PKCS #7 for the data to be signed.
2. Digesting the data to be signed according to PKCS #7.
3. Encoding a value of type DigestInfo according to PKCS #7 from the message digest.
4. Encrypting the DigestInfo encoding with a private key according to PKCS #1.
5. Encoding a value of type SignedData according to PKCS #7 from the first ContentInfo value, the encrypted message digest, and other information.
6. Encoding a value of type ContentInfo according to PKCS #7 from the SignedData value.

4.1 Encoding the inner ContentInfo value

Test User 1 encodes a value of type ContentInfo according to PKCS #7 for the data to be signed.

In this example, the content type is PKCS #7's data, which has the object identifier value {1 2 840 113549 1 7 1}. The content is an OCTET STRING value containing the ASCII string "Everyone gets Friday off." (The encoding does not specify ASCII; such an interpretation is left to the application.)

The BER-encoded inner ContentInfo value is:

```

30 28
 06 09                               contentType = data
    2a 86 48 86 f7 0d 01 07 01
  a0 1b                               [0] EXPLICIT
    04 19                               content = OCTET STRING value: "Everyone gets Friday off."
      45 76 65 72 79 6f 6e 65 20 67 65 74 73 20 46 72
      69 64 61 79 20 6f 66 66 2e

```

4.2 Digesting the data

Test User 1 digests the data to be signed according to PKCS #7.

The selected message-digest algorithm is MD2, as described in RFC 1321.

The input to the message-digest algorithm is the original ASCII string:

```
45 76 65 72 79 6f 6e 65 20 67 65 74 73 20 46 72 69 64 61 79 20 6f 66 66
2e
```

The resulting message digest is:

```
1d 32 de 00 9f 9c 56 ea 46 36 d3 9a af fd ae a1
```

4.3 Encoding a DigestInfo value

Test User 1 encodes a value of type `DigestInfo` according to PKCS #7 from the message digest.

The BER-encoded `DigestInfo` value is:

```
30 20
 30 0c
    06 08 2a 86 48 86 f7 0d 02 02
    05 00
 04 10
    1d 32 de 00 9f 9c 56 ea 46 36 d3 9a af fd ae a1
                                         digestAlgorithm
                                         algorithm = md2
                                         parameters = NULL
                                         digest
```

4.4 Encrypting the DigestInfo encoding

Test User 1 encrypts the `DigestInfo` encoding with his (or her) private key according to PKCS #1. Section 3.2 describes the RSA encryption process in detail. The resulting encrypted message digest is the following 64-octet string:

```
05 fa 6a 81 2f c7 df 8b f4 f2 54 25 09 e0 3e 84
6e 11 b9 c6 20 be 20 09 ef b4 40 ef bc c6 69 21
69 94 ac 04 f3 41 b5 7d 05 20 2d 42 8f b2 a2 7b
5c 77 df d9 b1 5b fc 3d 55 93 53 50 34 10 c1 e1
```

4.5 Encoding a SignedData value

Test User 1 encodes a value of type `SignedData` according to PKCS #7 from the inner `ContentInfo` value, the encrypted message digest, and other information. The other information includes:

- the issuer and the serial number of Test User 1's certificate (see Section 3.4);
- Test User 1's certificate;
- a message-digest algorithm identifier (RFC 1321's `md2`); and
- a message-digest encryption algorithm identifier (PKCS #1's `rsaEncryption`).

The BER-encoded SignedData value is:

```

30 82 02 3d
 02 01 01                               version = 1
 31 0e                               digestAlgorithms
 30 0c
    06 08 2a 86 48 86 f7 0d 02 02      algorithm = md2
    05 00                               parameters = NULL
 30 28 06 09 ... 6f 66 66 2e        content = inner ContentInfo
  a0 82 01 5e
    30 82 01 5a ... 26 9d 9b 16      certificates
  31 81 9b
    30 81 98
      02 01 01                         version = 1
      30 34
        30 2c 31 0b ... 74 69 6f 6e   issuerAndSerialNumber
        02 04 14 00 00 29             issuer
      30 0c
        06 08 2a 86 48 86 f7 0d 02 02  digestAlgorithm
        05 00                         algorithm = md2
      30 0d
        06 09                         digestEncryptionAlgorithm
          digestEncryptionAlgorithm = rsaEncryption
          2a 86 48 86 f7 0d 01 01 01
        05 00                         parameters = NULL
      04 40
        05 fa 6a 81 2f c7 df 8b f4 f2 54 25 09 e0 3e 84
        6e 11 b9 c6 20 be 20 09 ef b4 40 ef bc c6 69 21
        69 94 ac 04 f3 41 b5 7d 05 20 2d 42 8f b2 a2 7b
        5c 77 df d9 b1 5b fc 3d 55 93 53 50 34 10 c1 e1

```

4.6 Encoding a ContentInfo value

Test User 1 encodes a value of type ContentInfo according to PKCS #7 from the SignedData value.

The content type is PKCS #7's signedData, which has the object identifier value {1 2 840 113549 1 7 2}.

The BER-encoded ContentInfo value is:

```

30 82 02 50
  06 09 2a 86 48 86 f7 0d 01 07 02      contentType = signedData
  a0 82 02 41                           [0] EXPLICIT
  30 82 02 3d ... 34 10 c1 e1           content = SignedData value

```

(The full BER encoding is reproduced in Appendix A for reference.)

Revision history

June 3, 1991 version

The June 3, 1991 version is part of the initial public release of PKCS. It was published as NIST/OSI Implementors' Workshop document SEC-SIG-91-25.

November 1, 1993 version

The November 1, 1993 version incorporates several editorial changes, including the addition of a references section, Appendix A: Example signed-data encoding, and a revision history. It is updated to be consistent with the following versions of the PKCS documents:

PKCS #1: RSA Encryption Standard. Version 1.5, November 1993.

PKCS #5: Password-Based Encryption Standard. Version 1.5, November 1993.

PKCS #7: Cryptographic Message Syntax Standard. Version 1.5, November 1993.

PKCS #8: Private-Key Information Syntax Standard. Version 1.2, November 1993.

PKCS #10: Certification Request Syntax Standard. Version 1.0, November 1993.

The following substantive changes were made:

General: Names and keys are changed, consistent with external PKCS examples.

Section 3: Certification request examples are added. Extended certificate examples are removed.
